Version 1.2 | 2026-10-01 | HUDK 4054 Individual Assignment #2

Project status. The app runs on GitHub Pages and can export progress as JSON. This package documents that format for a proposed pilot. The example is synthetic; participant data collection is planned.

1. General information

Daily English Lab offers bilingual expressions, quizzes and branching conversations for everyday English practice. This proposal uses its progress exports to explore how learners use those activities.

Research question: What patterns of daily-expression practice, quiz accuracy and scenario completion appear in a small voluntary pilot?

- **Creator and data contact:** Zhenghui Yin, Teachers College, Columbia University; contact through [GitHub Issues](#).
- **ORCID:** [0009-0004-4769-1395](#).
- **Participants:** adult volunteers. Sample size, study duration, dates and collection location will be set before recruitment.
- **Coverage:** English and Chinese content about U.S. situations; English documentation. Keywords: learning analytics, English practice, browser progress.
- **Documentation date:** 2026-10-01. This coursework proposal has no external funding.

2. Data and files

One export is a snapshot of progress retained in one browser, not one row per learner or session. The planned study would collect one final export per participant. This package contains one fictional example and no participant records.

File	Contents
README.md	Project context, methods, access rules and dictionaries.
data_dictionary.csv	All 18 paths across the export's 12 top-level keys, using the five-column dictionary format shown in Section 5.
expression_dictionary.csv	The expression library's eight fields.
example_progress_SYNTHETIC.json	A manually created format example using existing expression IDs.
Daily_English_Lab_README.pdf	PDF reading copy.
assets/	Banner, badges, interface screenshot, workflow graphic and Carbon example.

The source repository contains `app.js`, 306 records in `data/expressions.js`, and 22 everyday settings with 311 tasks in `data/scenarios.js`. `data/marketEnglish.js` supplies a separate market-English module. These are app content, not learner observations.

2. Data and files (continued)

Real exports use `daily-english-lab-progress-YYYY-MM-DD.json`. The reviewed app uses storage key `daily-english-lab-state-v1`; its README labels the app V7. The dictionary is tied to the reviewed app.js blob SHA-1 `2dce96c1226dab44cec88b6ab16781a3e0a23887`. Recheck it if the export code changes.

3. Sharing and access

The [app](#) and [source repository](#) are public. Use **Export Progress** to download local JSON. The authored documentation, dictionaries and synthetic example are shared under [CC BY 4.0](#). This license does not apply to the app source or third-party badge assets. No explicit license file was found in the reviewed app repository.

Future participant exports would be collected through an institution-approved private channel after consent and any required ethics review. Keep originals and a restricted backup, analyze copies, and keep study codes and consent records separately. Set storage, retention and deletion rules before recruitment. GitHub would contain documentation and synthetic examples; sharing participant-derived results would require consent and disclosure review.

Documentation DOI: [10.5281/zenodo.23090958](https://doi.org/10.5281/zenodo.23090958). The Zenodo archive preserves this documentation package and synthetic example. A participant dataset DOI is not applicable yet. The archived version 1.2 files retain the earlier author label; the author metadata has been corrected to Zhenghui Yin.

4. Methods

How the app records progress

The app persists state to the browser `localStorage`. Quiz answers increment counters cumulatively. Correct answers and users can add marks indicating an expression is learned; users can delete these marks later. `sessions` tracks unique IDs of expressions learned or answered correctly by UTC day. Scenario counters track the number of starts and each possible ending; `completed` includes runs that succeeded or partially completed each scenario.

Export includes app name and export timestamp in the saved state. It does not track participant IDs, per-answer timestamps, time on task, demographics or proficiency test data. Browser resets, reset-and-imported data, and use by multiple people alters how one may wish to interpret the record.

Proposed collection and checks

Ask participants that consent to the study to only use one browser for the app and submit a single export to a pre-agreed upon location. Collect study codes outside the app and record if data was reset, imported, or shared separately. Exclude the market module from primary analysis and remove duplicates before summarizing.

Validate JSON syntax, app name, timestamp, IDs of known expressions, and nonnegative integer counters. For each module, enforce that `correct <= total` and `success <= completed <= runs`. Report duplicate IDs or IDs not matching a known expression.

Missing-value conventions are described in Section 5.

Planned analysis and limits

Summarize the current number of learned items, quiz accuracy ($100 * \text{correct} / \text{total}$), and scenario completion rate ($100 * \text{completed} / \text{runs}$). A missing or zero denominator results in the percentage being unavailable. Script analysis in Python 3 and note the version when saving analysis. Note the number of exports used and values missing. Counters are inflated by repeated practice; indicator variables for learned marks should not be considered validated measures of mastery. Such analysis can describe usage of the app, but cannot by itself show that users learn better or that the app had any effect.

5. Data dictionaries

Variable is a readable label; Variable name is the exact field or JSON path. Description gives the type and definition. None means no measurement unit.

Progress export

Dots indicate nested JSON paths. Counts are cumulative within the retained browser state and have no fixed upper bound. Missing keys must be flagged as unknown; [], {} and zero counters are valid empty values. IDs refer to the corresponding content library.

Variable	Variable name	Measurement unit	Allowed values	Description
Application name	app	None	Daily English Lab	String. Name of the exporting application.
Export time	exportedAt	UTC timestamp	ISO 8601 date-time	String. Snapshot export time; individual activities have no timestamps here.
Learned expression IDs	learned	IDs	Unique IDs in EXPRESSIONS; [] valid	String array. Current learned marks, set manually or after correct quiz answers. Marks can be removed.
Favorite expression IDs	favorites	IDs	Unique IDs in EXPRESSIONS; [] valid	String array. Expressions currently saved as favorites.
Dated expression records	sessions	UTC day and IDs	YYYY-MM-DD keys; arrays of expression IDs; {} valid	Object. Unique expression IDs marked learned or answered correctly on each UTC day; not all activity.
Correct daily answers	quiz.correct	answers	0 to quiz.total	Integer. Cumulative correct daily-expression answers.
All daily answers	quiz.total	answers	Nonnegative integer	Integer. Cumulative daily-expression answers, including repeated attempts.
Daily scenario starts	scenarios.runs	runs	Nonnegative integer	Integer. Cumulative everyday scenario starts.
Daily terminal outcomes	scenarios.completed	runs	0 to scenarios.runs	Integer. Everyday runs ending in success or partial completion.
Daily successes	scenarios.success	runs	0 to scenarios.completed	Integer. Everyday runs ending in success.
Learned market IDs	marketLearned	IDs	Unique IDs in MARKET_VOCAB; [] valid	String array. Market terms marked learned manually or after correct answers.
Favorite market IDs	marketFavorites	IDs	Unique IDs in MARKET_VOCAB; [] valid	String array. Market terms currently saved as favorites.
Correct market answers	marketQuiz.correct	answers	0 to marketQuiz.total	Integer. Cumulative correct market-English answers.
All market answers	marketQuiz.total	answers	Nonnegative integer	Integer. Cumulative market-English answers, including repeats.
Market scenario starts	marketScenarios.runs	runs	Nonnegative integer	Integer. Cumulative market scenario starts.
Market terminal outcomes	marketScenarios.completed	runs	0 to marketScenarios.runs	Integer. Market runs ending in success or partial completion.
Market successes	marketScenarios.success	runs	0 to marketScenarios.completed	Integer. Market runs ending in success.
Display theme	theme	None	light; dark; pink	String. Saved display preference; excluded from learning analysis.

5. Data dictionaries (continued)

Expression library

Each row in `data/expressions.js` describes one learning item. Progress IDs link to `id`. All eight fields are expected; flag absent fields as unknown. An empty tags array is valid. Difficulty labels describe content, not a participant's proficiency.

Variable	Variable name	Measurement unit	Allowed values	Description
Expression identifier	<code>id</code>	ID	Unique nonempty identifier	String. Links content to learned, favorites and sessions.
English expression	<code>phrase</code>	None	English text	String. Expression presented for practice.
Chinese meaning	<code>meaning_cn</code>	None	Chinese text	String. Chinese explanation of the expression.
English example	<code>example</code>	None	English text	String. Example sentence containing the expression.
Chinese example	<code>example_cn</code>	None	Chinese text	String. Chinese translation of the example sentence.
Content category	<code>category</code>	None	Category labels in the library	String. Topic group used for browsing and progress summaries.
Assigned difficulty	<code>level</code>	label	A1; A2; B1; B2	String. App-assigned difficulty; not independently validated or a learner proficiency score.
Search tags	<code>tags</code>	None	Content tags; [] valid	String array. Keywords used to describe or find expressions.

Synthetic example

The full JSON example contains all 12 top-level keys. Its dates and counts are fictional and demonstrate the format.

6. Metadata standard

This README follows **DDI-Codebook 2.6** concepts for documenting a study, its files, access conditions and variables. The dictionaries follow OSF's guidance. This is a Markdown document organized around DDI concepts, not a validated DDI XML record.

7. Assignment reflection

Which metadata standard did you choose and why?

I selected DDI-Codebook because the framework links variable definitions to both the purpose of the study as well as how and why the data were collected. That was compatible with my learning analytics initiative where a counter label isn't necessarily descriptive of what it counts.

Which template/software did you use?

Structurally, I used Make a README, Awesome README, Markdownify, and Rachael Abraham's ReadMe File as references. I used OSF's How to Make a Data Dictionary to properly define variables and create rules for missing values. Shields.io hosts all of the badges, and Carbon generated the synthetic JSON excerpt. Codex assisted with formatting.

What was most challenging, and how did you address it?

The hardest thing for me was creating the specification before gathering data from participants. By utilizing the app's current export format to determine the variables, labeling the sample JSON as synthetic, separating the app's current offerings from the proposed study, and marking the DOI as pending assignment, I was able to outline what currently exists without showcasing planned features as finished.
